

Autosomal dominant inheritance in pedigree and experiment, examples of traits in man

Characteristics of AD pedigrees

- direct transmission from an affected parent to an affected child (= does not skip generations)
- males and females are equally likely to be affected
- both males and females transmit the disease
- transmission from father to son

Examples of pedigrees

Examples

- achondroplasia,
- brachydactyly,
- polycystic kidney disease,
- familial hypercholesterolemia,
- dentinogenesis imperfecta,
- osteogenesis imperfecta,
- dysostosis cleidocranialis

Important feature of AD inheritance in pedigree (!!)

Many, maybe majority of human traits/diseases with AD inheritance (e.g. dysmorphic syndromes), are AD but with incomplete dominance. Thus, all individuals with the defect/disease in pedigrees (and in population) are heterozygotes Aa . The defect/disease is much more severe in homozygous individuals (AA), often with lethal effect in homozygous fetuses.

AD inheritance in hybridization experiment

In experimental procedure, pure lines (e.g. inbred strains) are chosen based on difference in a trait (purple vs. white flowers, yellow vs. green seeds, coloured vs. albino fur). Parental generation pairs are formed combining one individual from one and an individual from the other line. They are crossed for obtaining F_1 hybrids. By intercrossing the F_1 individuals the F_2 generation is obtained, where phenotypes are segregating in ratio 3 to one (dominant vs. recessive form of the trait). These 3/4 are corresponding to phenotype of F_1 hybrids - the F_1 generation express the dominant form of the trait as well.

In a general population with uniform (wild) phenotype, an individual with an exceptional (newly appearing) form of the phenotype can be tested by hybridization experiment, too, if he/she/it express the dominant or recessive form of the trait. If this new, different form of a trait is dominant, then this hybridization test (crossing with anyone individual with normal, common, wild phenotype in the population) represents de facto a backcross repeatedly resulting in phenotypic ratio 1 to 1.
