

# Spontaneous bacterial peritonitis

The printable version is no longer supported and may have rendering errors. Please update your browser bookmarks and please use the default browser print function instead.

Spontaneous bacterial peritonitis is a bacterial infection of the ascites without any detectable or surgically treatable source of the infection. This is a common complication of ascites (30%) of cirrhotic origin.

## Etiology and pathogenesis

- The source of the infection is probably the intestine - the infection passes through the intact intestinal wall through translocations
- ascites with low opsonic activity are more susceptible to spontaneous bacterial peritonitis,
- infectious agents are mostly facultative anaerobic gram negative intestinal bacteria: *E. coli*, *Klebsiella*, *Enterobacter*, *Proteus*.

## Clinical manifestation

- Signs are variable + mostly insignificant,
- infection can manifest with ↑ accumulation of the ascites + failure of the diuretic treatment, or with the liver insufficiency,
- subfebrile temperature + diffuse abdominal pain,
- often manifest after the bleeding of the esophageal varices,
- untreated bacterial peritonitis has lethality about 30 %.

## Diagnostics

- Diagnostic paracentesis with ascites examination: cultivation, leukocytes  $> 0,4 \times 10^9/l$  → start treatment.

## Therapy

- Cephalosporins of the third generation (cefotaxime, 2 g every 8 hours), albumin (prevention of the hypovolemia - hepatorenal syndrome),
- selective intestinal decontamination with the non-absorbable antibiotics (norfloxacin 400 g) – prevention.

## Prognosis

- Poor (relapse, worsening of liver + renal function).
