

Decerebral rigidity

The printable version is no longer supported and may have rendering errors. Please update your browser bookmarks and please use the default browser print function instead.

Template:Heslo

Decerebrate rigidity arises from a bilateral lesion **at the level of the mesencephalon' or caudal diencephala**. It is the result of removing the influence of the inhibitory part of the descending reticular formation. This will increase the tone of the extensors. Rather than rigidity, it is *extension spasticity*. The upper limbs are *extended*, the forearm is in pronation, the wrist is in flexion. The lower limbs are *extended*. opisthotonus can occur.^[1]
